

PERSONAL INVESTMENT PORTFOLIO TRACKER

Self-Initiated FinTech & Financial Analysis Project

Excel-based portfolio tracking, valuation and dashboard analysis

Project Type	Self-Initiated Portfolio Project
Primary Tool	Microsoft Excel
Focus Areas	Portfolio Tracking • Financial Analysis • Data Visualization
Prepared By	Anuj

Purpose: demonstrate practical finance, Excel and analytical skills for internship applications.

1. Project Overview

The Personal Investment Portfolio Tracker is a self-initiated Excel project designed to demonstrate practical financial analysis and data-management skills. The tracker records investment transactions, calculates holdings and cost including brokerage, monitors current portfolio value, measures unrealized profit/loss and returns, and presents the results through an Excel dashboard.

Why I Built It

The project was created as a practical portfolio piece rather than an academic assignment. The objective was to turn basic knowledge of investments and Excel into a working finance-oriented tool that can be explained and demonstrated during internship applications and interviews.

2. Objectives

- Create a structured transaction log for buy/sell activity.
- Automatically calculate current holdings using transaction data.
- Include brokerage in the investment cost basis.
- Calculate current value, unrealized P/L and stock-level returns.
- Measure portfolio allocation using current market value.
- Build an analysis layer that summarizes the portfolio.
- Create a visual dashboard for quick financial interpretation.

3. Tools & Skills Demonstrated

Area	Implementation
Spreadsheet tool	Microsoft Excel
Core functions	SUM, SUMIFS, IFERROR, COUNTA
Data management	Excel Table, structured references, data validation
Financial analysis	Investment cost, current value, unrealized P/L, return %, portfolio weight
Visualization	Doughnut chart and column charts
Presentation	Dashboard layout, KPI cards, conditional formatting

4. System Workflow

The workbook is organized into five layers so that raw transaction data flows into calculations and then into management-level insights:

The Read Me sheet documents the purpose, features, limitations and future improvements.

5. Methodology & Financial Logic

Transaction Cost: $\text{Quantity} \times \text{Price per Share} + \text{Brokerage}$. This keeps brokerage visible and includes it in the holding cost basis.

Current Value: $\text{Quantity} \times \text{Current Price}$.

Unrealized P/L: $\text{Current Value} - \text{Total Invested}$.

Return %: $\text{Unrealized P/L} \div \text{Total Invested}$.

Portfolio Weight: $\text{Individual Current Value} \div \text{Total Portfolio Current Value}$.

6. Final Portfolio Snapshot

Metric	Final Result
Total invested (including brokerage)	■32,980
Total brokerage	■80
Current portfolio value	■34,120
Total unrealized P/L	■1,140
Overall return	3.46%
Number of holdings	4

7. Stock-Level Analysis

Stock	Qty	Invested	Current	P/L	Return	Weight
Reliance Industries	5	■7,020	■7,250	■230	3.28%	21.25%
HDFC Bank	8	■7,620	■7,760	■140	1.84%	22.74%
TCS	3	■9,320	■9,750	■430	4.61%	28.58%
Infosys	6	■9,020	■9,360	■340	3.77%	27.43%

TCS has the largest portfolio weight at approximately 28.58% and the highest stock-level return at approximately 4.61% in the sample portfolio. HDFC Bank has the lowest stock-level return at approximately 1.84%. These observations describe the current sample data and are not investment recommendations.

8. Dashboard & Visualization

The dashboard converts the underlying calculations into a compact management view. Four KPI areas show total invested, current portfolio value, total unrealized P/L and overall return.

- Portfolio Allocation: a doughnut chart shows how current portfolio value is distributed across the four holdings.
- Profit/Loss by Stock: a column chart compares unrealized P/L across holdings.
- Invested vs Current Portfolio Value: a column chart compares total cost with current portfolio value.

Supporting tables beneath the KPI section provide the values used by the visualizations, making the dashboard traceable to the underlying workbook calculations.

9. Limitations

- Current market prices are entered manually rather than retrieved through a live market-data connection.
- The current version focuses on unrealized P/L and does not calculate realized P/L for sell transactions.
- Taxes and detailed transaction charges beyond the modeled brokerage are outside the current scope.
- The sample portfolio is illustrative and is intended to demonstrate the tracker's functionality.

10. Future Improvements

- Connect the workbook to automatic market-price updates.
- Add Python integration for automated data collection and analysis.
- Introduce realized P/L, tax and transaction-cost reporting.
- Add portfolio risk metrics such as volatility and Sharpe ratio.
- Build stock-level performance and benchmark comparison.
- Develop a web-based dashboard for easier portfolio monitoring.

11. Skills & Learning Outcomes

This project strengthened practical understanding of portfolio mechanics, cost-basis calculation, unrealized P/L, percentage returns and portfolio allocation. It also provided hands-on experience in structuring financial data, using Excel formulas and tables, applying validation and conditional formatting, and communicating financial information through dashboards.

12. Conclusion

The Personal Investment Portfolio Tracker demonstrates how a simple spreadsheet can be structured into a usable financial-analysis tool. The completed workbook connects transaction data with holdings, analysis and visual reporting, while keeping the calculations transparent. As a self-initiated portfolio project, it provides a practical foundation for progressing from Excel-based finance analysis toward Python-based market data analysis and more advanced FinTech projects.

Project documentation prepared for portfolio and internship applications.
